Script-Controlled ACL – Restrict Record Access Based on Field Value

Requirement Analysis Phase:

The requirement analysis phase identifies the access control requirements for the Institution Details table in Service Now. The main objective is to restrict record access based on the value of a specific field.

Functional Requirements:

The system should check the field value before allowing access to a record.

Access should be granted only when the required condition is satisfied.

The ACL should control the read access of records.

The system should deny access when the field value does not meet the defined condition.

The access control logic should be implemented using an ACL script.

User Requirements:

Authorized users should be able to view permitted records.

Unauthorized users should not be able to view restricted records.

The access decision should be automatic based on the field value.

Users should receive consistent access behaviour for different records.

Technical Requirements:

Service Now platform is required for implementation.

An appropriate table and field must be identified.

A record-level Read ACL should be created.

A script condition should be added to the ACL.

The ACL should be tested with different field values and user roles.

Security Requirements:

Restricted records must not be accessible to unauthorized users.

The ACL condition must be applied consistently.

Access should be controlled according to the defined business rule.

The implementation should reduce unauthorized record visibility.

Expected Outcome

The final system should allow users to access records only when the specified field value satisfies the defined condition. Records that do not satisfy the condition should be restricted automatically.
